## Abstract

Hausmannite and manganosite were identified at the Čierna baňa manganese deposit near Čučma, Slovenské Rudohorie Mts., Gemic Superunit, Slovak Republic. Hausmannite occurs as black, fine-grained masses up to 10 cm in size. It contains aggregates of manganosite and microscopic barite, rhodonite, rhodochrosite and spessartine inclusions. The refined unit-cell parameters of hausmannite from the powder X-ray diffraction data (for the tetragonal space group  $I4_1/amd$ ) are  $a = 5.786(11)$ ,  $c = 9.411(2)$  Å with  $V = 315.1(6)$  Å<sup>3</sup>. Manganosite forms anhedral, emerald to dark green grains and aggregates up to 2 mm in size embedded in hausmannite matrix. It is first documented occurrence of this species in Slovakia. The refined unit-cell parameters of manganosite from the powder X-ray diffraction data (for the cubic space group  $Fm\bar{3}m$ ) are  $a = 4.445(1)$  Å with  $V = 87.801(2)$  Å<sup>3</sup>. Its chemical composition is close to the end member with the empirical formula (average of 6 point analyses) corresponding to  $(Mn_{0.99}Mg_{0.01})_{\Sigma 1.00}O_{1.00}$  on the basis of O = 1.

**Key words:** hausmannite, manganosite, manganese oxides, X-ray powder data, chemical composition, Čučma, Gemic Superunit, Slovak Republic
